# Abstract

We provide a simple and intuitive theory to explain how coupling a molecule to an optical cavity can modify ground-state chemical reactivity by exploiting intrinsic quantum behaviors of light-matter interactions. Using the recently developed Polarized Fock States representation, we demonstrate that the change of the groundstate potential is achieved due to the scaling of diabatic electronic couplings with the overlap of the polarized Fock states. Our theory predicts that for a protontransfer model system, the ground state barrier height can be modified through light-matter interactions when the cavity frequency is in the electronic excitation range. Our simple theory explains several recent computational investigations that discovered the same effect. We further demonstrate that under the deep strong coupling limit of the light and matter, the polaritonic ground and first excited eigenstates become the Mulliken-Hush diabatic states, which are the eigenstates of the dipole operator. This work provides a simple but powerful theoretical framework to understand how strong coupling between molecule and cavity can modify ground state reactivities.

#### Introduction

Coupling molecules to a quantized radiation field inside an optical cavity creates a set of photonmatter hybrid states, so-called polaritons. These polariton states hybridize the curvatures from both the ground and the excited electronic states and

have shown a great promise to alter the photochemistry of molecules. <sup>1–4</sup> Unlike traditional photochemistry, which uses light as an energy source, polariton chemistry uses quantized photons as active chemical catalysts to significantly change the shape of the potential energy surface in molecular systems, and thus, open up new possibilities to tune and control chemical reactions. <sup>5–8</sup>

Theoretical investigations play a vital role in understanding the fundamental limits and the basic principle of new chemical reactivities achieved by polariton chemistry. <sup>7–10</sup> In particular, the molecule-cavity interactions have often been described as the following dipole gauge Hamiltonian

$$\hat{\mathcal{H}} = \hat{\mathcal{H}}_{\mathrm{M}} + \hat{H}_{\mathrm{ph}} + \chi \cdot \hat{\boldsymbol{\mu}} (\hat{a}^{\dagger} + \hat{a}) + \frac{1}{\hbar \omega_{c}} (\chi \cdot \hat{\boldsymbol{\mu}})^{2}, (1)$$

where  $\hat{\mathcal{H}}_{\mathrm{M}}$  is the molecular Hamiltonian,  $\hat{H}_{\mathrm{ph}}$  is

the photon field Hamiltonian,  $\hat{a}^{\dagger}$  and  $\hat{a}$  are the raising and lowering operators of the cavity field, and  $\hat{\mu}$  is the dipole operator of the molecule. Further,  $\chi = \chi \hat{\mathbf{e}}$ , where  $\chi$  describes the coupling strength, and ê indicates the cavity field polarization direction. This Hamiltonian predicts that there will be couplings between the photon-dressed states, for example,  $|q,1\rangle \equiv |q\rangle \otimes |1\rangle$  (ground electronic state with 1 photon) and  $|e,0\rangle \equiv |e\rangle \otimes |0\rangle$ (excited electronic state with 0 photons), through  $\langle g, 1|\hat{\boldsymbol{\mu}}(\hat{a}^{\dagger} + \hat{a})|e, 0\rangle = \boldsymbol{\mu}_{ae}\langle 1|(\hat{a}^{\dagger} + \hat{a})|0\rangle.$  When the energy of these two states are very close, the  $|q,1\rangle$  and  $|e,1\rangle$  states hybridize, leading to the formation of polariton states. Using such a simple Hamiltonian, it has been shown that the presence of the cavity can suppress<sup>11</sup> or enhance<sup>8,12</sup> photo-isomerizations, <sup>11–13</sup> increase charge transfer rates by orders of magnitude, 14-16 modify potential energy landscapes even with no photon in the cavity, 8,11,17-19 enhance electron-phonon coupling strength, 20 accelerate singlet fission kinetics, <sup>21</sup> remotely control chemical reactions, <sup>22</sup> enhance excitation energy transfer processes, 16,23,24 and create new polariton induced conical intersections. 8,18,25,26 All of these emerging features of the polariton chemistry demonstrate a great promise to control and tune chemical reactivities, as the cavity quantum electrodynamics (QED) processes take advantage of the quantum nature of the light and its interaction with the molecular system.

Recently, several theoretical works have demonstrated that the *ground state* of a molecular system can be significantly modified by coupling to a cavity photon mode with a photon frequency in the electronic excitation range. 27-34 In particular, Ref. 35 demonstrates that the aminopropenal proton transfer reaction barrier can be modified by coupling the system with the cavity. Note that the cavity frequency in these studies is chosen to be in the range of electronic excitation (in terms of energy, a couple of eV), thus different than the recently explored vibrational strong coupling (VSC) regime<sup>36,37</sup> (in terms of energy, a couple of meV). These modifications are caused by indirect couplings between different photon-dressed states, due to the presence of both transition and permanent dipoles. <sup>38</sup> For example, the  $|a,0\rangle$  state couples with  $|g,1\rangle$  through  $\langle g,1|\hat{\mu}(\hat{a}^{\dagger}+\hat{a})|g,1\rangle =$  $\mu_{qq}\langle 1|(\hat{a}^{\dagger}+\hat{a})|0\rangle$ , and  $|g,1\rangle$  couples to the  $|e,0\rangle$ through  $\mu_{ae}\langle 1|(\hat{a}^{\dagger}+\hat{a})|0\rangle$ . As such, the  $|g,0\rangle$  and the  $|e,0\rangle$  states are indirectly coupled to each other (through the light-matter interactions), and the

ground state properties can also be significantly influenced under the strong light-matter interaction coupling strength. Further, the dipole selfenergy (DSE) term (see Eq. 1, the last term) could also significantly influence the ground state properties and reactivities, as demonstrated in Ref. This is because the DSE operator can be expressed as  $\langle g|\hat{D}|e_i\rangle = \frac{\lambda^2}{2} \sum_{\alpha} \hat{\mu}_{g\alpha} \hat{\mu}_{\alpha e_i}$  where  $|\alpha\rangle \in \{|g\rangle, |e_1\rangle ... |e_i\rangle ... \}$ . One can clearly see that the DSE term is able to connect electronic adiabatic states far away in energy. However, an intuitive and simple understanding of cavity modification of the molecular ground state is still missing. As such, the cavity-modified chemical reactivity in the ground state is an interesting new direction, but not well understood due to those indirect effects as we mentioned above.

In this paper, we provide a new theory and mechanism to explain how the ground state chemical reactivity for a molecular system can be modified by coupling to the cavity with electronic excitation frequency. Our theory is based on the recently developed Polarized Fock States representation, which are shifted cavity Fock states associated to each specific electronic state. These PFSs are non-orthogonal to each other but provide a compact description of the photonic Hilbert space. Using the recently developed Polarized Fock States representation, we demonstrate that the change of the ground-state potential is achieved due to the scaling of diabatic electronic couplings with the overlap of the polarized Fock states. As the light-matter coupling increases, the diabatic electronic coupling is effectively reduced, resulting in a ground polaritonic potential energy surface that resembles the diabatic potential (associated with the dipole operator's eigenstate).

Our theory predicts that for a proton coupled electron transfer model system (Shin-Metiu model <sup>39</sup>), the ground state barrier height can be modified through light-matter interactions when the cavity frequency is in the electronic excitation range. This novel change in the ground-state chemical reactivity is achieved through electronic strong coupling as opposed to the more common use of vibrational strong coupling for modifying the ground state. <sup>36,37,40–42</sup> Our simple theory explains several recent computational investigations that discovered the same effect. <sup>35</sup> We further demonstrate that under the deep strong coupling limit of the light and matter, the polaritonic ground and first excited eigenstates become the Mulliken-Hush dia-

batic states, which are the eigenstates of the dipole operator. This work provides a simple but powerful theoretical framework to understand how strong coupling between molecule and cavity can modify ground state reactivities.

# Theoretical Framework

# Theory of Polarized Fock States

We start by introducing the Pauli-Fierz (PF) non-relativistic QED Hamiltonian  $^{43-45}$  to describe the light-matter interaction. The PF Hamiltonian can be rigorously derived  $^{15,44,46}$  by applying the Power-Zienau-Woolley (PZW) Gauge transformation  $^{47,48}$  and a unitary phase transformation  $^{46}$  on the minimal-coupling Hamiltonian in the Coulomb gauge (*i.e.* the "p·A" Hamiltonian) under the long-wavelength limit. A rigorous derivation is provided in the Appendix. For a molecule coupled to a single photon mode inside an optical cavity, the PF Hamiltonian is

$$\hat{H}_{PF} = \hat{H}_{M} + \frac{1}{2}\hat{p}^{2} + \frac{1}{2}\omega_{c}^{2}\left(\hat{q} + \sqrt{\frac{2}{\hbar\omega_{c}^{3}}}\boldsymbol{\chi}\cdot\hat{\boldsymbol{\mu}}\right)^{2}$$
(2)  
$$= \hat{H}_{M} + \left(\hat{a}^{\dagger}\hat{a} + \frac{1}{2}\right)\hbar\omega_{c} + \boldsymbol{\chi}\cdot\hat{\boldsymbol{\mu}}(\hat{a}^{\dagger} + \hat{a}) + \frac{1}{\hbar\omega_{c}}(\boldsymbol{\chi}\cdot\hat{\boldsymbol{\mu}})^{2},$$

which is Eq. 1 in the Introduction. In the last line of Eq. 2,  $\hat{H}_{\rm M}$  represents the molecular Hamiltonian, the second term  $\hat{H}_{\rm ph}=\left(\hat{a}^{\dagger}\hat{a}+\frac{1}{2}\right)\hbar\omega_{\rm c}$  represents the Hamiltonian of the vacuum photon field inside the cavity with the frequency  $\omega_{\rm c}$ , the third term describes the light-matter interaction in the electric-dipole "d·E" form ,<sup>48</sup> with  $\chi=\sqrt{\frac{\hbar\omega_{\rm c}}{2\varepsilon_0\mathcal{V}}}\hat{\mathbf{e}}\equiv\chi\hat{\mathbf{e}}$  characterizing the light-matter coupling vector oriented in the direction of polarization unit vector  $\hat{\mathbf{e}}$ ,  $\mathcal{V}$  as the quantization volume for the photon field, and  $\varepsilon_0$  as the permittivity inside the cavity. Further,  $\hat{a}^{\dagger}$  and  $\hat{a}$  are the photon creation and annihilation operator,  $\hat{q}_{\rm c}=\sqrt{\hbar/2\omega_{\rm c}}(\hat{a}^{\dagger}+\hat{a})$  and  $\hat{p}_{\rm c}=i\sqrt{\hbar\omega_{\rm c}/2}(\hat{a}^{\dagger}-\hat{a})$  are the photonic coordinate and momentum operator, respectively.

The total dipole operator of the entire molecule is

$$\hat{\boldsymbol{\mu}} = \sum_{k} z_k \hat{\mathbf{x}}_k,\tag{3}$$

where  $z_k$  is the charge for the  $k_{\rm th}$  charged particle. Throughout this study, we assume that  $\hat{\bf e}$  aligns with the direction of  $\hat{\boldsymbol{\mu}}$ . The last term is the dipole self-energy (DSE), which describes how the polarization of the matter acts back on the photon field.

The PF Hamiltonian  $\hat{H}_{PF}$  (Eq. 2) is what we expressed in Eq. 1 of the Introduction.

The matter Hamiltonian is expressed as follows

$$\hat{H}_{\mathrm{M}} = \hat{\mathbf{T}} + \hat{V}(\hat{\mathbf{x}}) = \sum_{j} \frac{1}{2m_{j}} \hat{\mathbf{p}}_{j}^{2} + \hat{V}(\hat{\mathbf{x}}_{j}), \qquad (4)$$

where j is the index of the  $j_{\rm th}$  charged particle (including all electrons and nuclei), with the corresponding mass,  $m_j$ , and canonical momentum,  $\hat{\mathbf{p}}_j = -i\hbar \nabla_j$ . We denote electronic coordinate with  $\hat{\mathbf{r}}$ , and nuclear coordinate with  $\hat{\mathbf{r}}$ , and use  $\hat{\mathbf{x}}_j \in \{\mathbf{r}_j, \mathbf{R}_j\}$  to represent either the electron or nucleus, with  $\hat{\mathbf{x}}$  being the coordinate operator for all charged particles. Further,  $\hat{\mathbf{T}} = \hat{\mathbf{T}}_{\mathbf{R}} + \hat{\mathbf{T}}_{\mathbf{r}}$  is the kinetic energy operator for all charged particles, where  $\hat{\mathbf{T}}_{\mathbf{R}}$  and  $\hat{\mathbf{T}}_{\mathbf{r}}$  represent the kinetic energy operator for nuclei and for electrons, respectively. Further,  $\hat{V}(\hat{\mathbf{x}})$  is the potential operator that describes the Coulombic interactions among the electrons and nuclei. The electronic Hamiltonian is often defined as

$$\hat{H}_{\rm el} = \hat{H}_{\rm M} - \hat{\mathbf{T}}_{\mathbf{R}} = \hat{\mathbf{T}}_r + \hat{V}(\hat{\mathbf{x}}),\tag{5}$$

which includes the kinetic energy of electrons, electron-electron interactions, electron-nuclear interactions, and nuclear-nuclear interactions. The essential task of the electronic structure community is focused on solving the eigenstates of  $\hat{H}_{el}$  at a particular nuclear configuration  $\mathbf{R}$  as follows

$$\hat{H}_{\rm el}|\Phi_{\alpha}(\mathbf{R})\rangle = E_{\alpha}(\mathbf{R})|\Phi_{\alpha}(\mathbf{R})\rangle,$$
 (6)

where  $E_{\alpha}(\mathbf{R})$  is commonly referred to as the  $\alpha_{\rm th}$  potential energy surface (PES) or adiabatic energy, and  $|\Phi_{\alpha}(\mathbf{R})\rangle$  is commonly referred to as the  $\alpha_{\rm th}$  adiabatic electronic state. The matrix elements of the total dipole operators can be obtained using the adiabatic states as

$$\mu_{\alpha\beta}(\mathbf{R}) = \langle \Phi_{\alpha}(\mathbf{R}) | \hat{\boldsymbol{\mu}} | \Phi_{\beta}(\mathbf{R}) \rangle.$$
 (7)

For  $\alpha \neq \beta$ ,  $\mu_{\alpha\beta}(\mathbf{R})$  is referred to as the transition dipole between state  $|\Phi_{\alpha}\rangle$  and  $|\Phi_{\beta}\rangle$ , while  $\mu_{\alpha\alpha}(\mathbf{R})$  is commonly referred to as the permanent dipole for state  $|\Phi_{\alpha}\rangle$ .

In a similar sense of defining the electronic Hamiltonian and corresponding eigenvalue equation for the matter, one can define the polaritonic Hamiltonian  $^{9,30,49}$  as  $\hat{H}_{\rm pl} \equiv \hat{H}_{\rm PF} - \hat{\mathbf{T}}_R$ , which includes all operators of molecules and cavity, except for the nuclear kinetic energy operator  $\hat{\mathbf{T}}_R$ . As

such, the polariton state is defined as the eigenstate of  $\hat{H}_{\rm pl}$  through the following eigenvalue problem

$$\hat{H}_{\rm pl}|\Psi_J(\mathbf{R})\rangle \equiv (\hat{H}_{\rm PF} - \hat{\mathbf{T}}_R)|\Psi_J(\mathbf{R})\rangle = \mathcal{E}_J(\mathbf{R})|\Psi_J(\mathbf{R})\rangle,$$
(8)

where  $\hat{H}_{\rm pl} \equiv \hat{H}_{\rm PF} - \hat{\mathbf{T}}_R$  is the polariton Hamiltonian,  $|\Psi_J(\mathbf{R})\rangle$  is the polariton eigenstate, and  $\mathcal{E}_J(\mathbf{R})$  is the polariton potential energy surface. As can be seen clearly, both  $|\Psi_J(\mathbf{R})\rangle$  and  $\mathcal{E}_J(\mathbf{R})$  parametrically depends on the nuclear configuration  $\mathbf{R}$ . We denote  $|\Psi_0(\mathbf{R})\rangle$  as the ground state of  $\hat{H}_{\rm pl}$ .

Next, we briefly introduce the idea of the Polarized Fock states, whereas the details for this theoretical development can be found in Ref. 38. In particular, we use the Mulliken-Hush diabatic representation to express the molecular Hamiltonian as well as the PF QED Hamiltonian. These Mulliken-Hush diabatic states  $\{|\mu_i\rangle\}$  are the dipole operator's eigenstates, such that

$$\hat{\boldsymbol{\mu}} = \sum_{i} \boldsymbol{\mu}_{i}(\mathbf{R}) |\mu_{i}\rangle\langle\mu_{i}|, \qquad (9)$$

where  $\mu_i$  is eigen-dipole value associated with the state  $|\mu_i\rangle$ . These  $|\mu_i\rangle$  states can be obtained from the direct diagonalization of the  $\hat{\mu}$  matrix in the adiabatic representation (with the matrix element expressed in Eq. 7). A good example of  $\mu_i$  could be the ionic and covalent dipole for a diatomic molecule, whereas the  $\mu_{\alpha\beta}$  are the transition and permanent dipoles (see Fig. 1 of Ref. 38)

Using the MH diabatic states, the matter Hamiltonian in Eq. 4 can be expressed as

$$\hat{\mathcal{H}}_{\mathrm{M}} = \hat{T}_{\mathbf{R}} + \sum_{i} V_{ii}(\mathbf{R}) |\mu_{i}\rangle\langle\mu_{i}| + \sum_{i \neq j} V_{ij}(\mathbf{R}) |\mu_{i}\rangle\langle\mu_{j}|,$$
(10)

where we have used the MH diabatic basis and  $V_{ii}(\mathbf{R})$  represents the diabatic potentials,  $V_{ij}(\mathbf{R})$  represents the diabatic coupling.

The PF Hamiltonian in Eq. 2 under a finite set of the  $|\mu_i\rangle$  basis is expressed as

$$\hat{\mathcal{H}}_{PF} = \hat{H}_{M} + \frac{\hat{p}_{c}^{2}}{2} + \sum_{i} \frac{\omega_{c}^{2}}{2} (\hat{q}_{c} + q_{i}^{0}(\mathbf{R}) |\mu_{i}\rangle\langle\mu_{i}|)^{2},$$
(11)

where the diabatic state-specific shift  $q_i^0(\mathbf{R})$  is

$$q_i^0(\mathbf{R}) = \sqrt{\frac{2}{\hbar\omega_c^3}} \mathbf{\chi} \cdot \boldsymbol{\mu}_i(\mathbf{R}). \tag{12}$$

We notice that the photon field is described as

a displaced Harmonic oscillator that is centered around  $-q_i^0(\mathbf{R})$ . This displacement can be viewed as a *polarization* of the photon field due to the presence of the molecule-cavity coupling, such that the photon field corresponds to a non-zero (hence polarized) vector potential, in contrast to the vacuum photon field.

We introduce the polarized Fock state (PFS)  $|n_i(\mathbf{R})\rangle \equiv |n_i\rangle$  as the Fock state of a displaced Harmonic oscillator, with the displacement  $-q_i^0 = -\sqrt{\frac{2}{\hbar\omega_c^3}}\boldsymbol{\chi}\cdot\boldsymbol{\mu}_i(\mathbf{R})$  specific to the diabatic state  $|\mu_i\rangle$  such that

$$|n_i\rangle = e^{-i(-q_i^0)\hat{p}/\hbar}|n\rangle = e^{iq_i^0\hat{p}/\hbar}|n\rangle,$$
 (13)

where  $n_i = 0, 1, 2..., \infty$  is the quantum number for the PFS. Compared to the vacuum's Fock state  $|n\rangle$ , this PFS depends on the diabatic state (or more generally, the eigenstate of  $\hat{\mu}$ ) of the molecule, and the position of the nuclei (through the **R** dependence in  $\mu_i(\mathbf{R})$ ). Due to the electronic statedependent nature of the polarization, the PFS associated with different electronic diabatic states become non-orthogonal, <sup>38</sup> i.e.,  $\langle n_i | m_j \rangle \neq \delta_{ij} \delta_{nm}$ .

To remove this shift of the photonic coordinate, a unitary transformation can be formed as

$$\hat{\mathcal{U}}_{\text{pol}} = \exp\left\{ \left[ \frac{i}{\hbar} \sum_{i} q_i^0(\mathbf{R}) |\mu_i\rangle \langle \mu_i | \hat{p}_c \right] \right\}, \quad (14)$$

where Eq. 14 is a shift operator of the form  $\hat{\mathcal{U}}_s = \exp[iq_0\hat{p}/\hbar]$  such that it shifts an arbitrary operator  $\hat{O}(\hat{q})$  by an amount  $q_0$ ,  $\hat{\mathcal{U}}_s^{\dagger}\hat{O}(\hat{q})\hat{\mathcal{U}}_s = \hat{O}(\hat{q} - q_0)$ .

The polariton Hamiltonian under the Polarized Fock State (PFS) representation can then be written as

$$\hat{\mathcal{H}}_{\text{pl}} = \hat{\mathcal{U}}_{\text{pol}}^{\dagger} (\hat{\mathcal{H}}_{\text{PF}} - \hat{T}_{\mathbf{R}}) \hat{\mathcal{U}}_{\text{pol}}$$

$$= \sum_{i,n_i} \left( V_{ii}(\mathbf{R}) + (n_i + \frac{1}{2}) \hbar \omega_{\text{c}} \right) |\mu_i, n_i\rangle \langle n_i, \mu_i|$$

$$+ \sum_{n_i, m_j, i \neq j} \langle m_j | n_i \rangle V_{ij}(\mathbf{R}) |\mu_i, n_i \rangle \langle m_j, \mu_j|.$$
(15)

The detailed expression of  $\hat{\mathcal{U}}_{\mathrm{pol}}^{\dagger}\hat{\mathbf{T}}_{\mathbf{R}}\hat{\mathcal{U}}_{\mathrm{pol}}$  can be found in Ref. 38. In Eq. 15, one can clearly see that as the light-matter coupling strength  $\chi$  increases, the overlap function between the displaced harmonic oscillators decreases for different diabatic states. This is because that the state-specific displacement,  $q_i^0$ , increases linearly with  $\chi$ , causing  $\langle m_i | n_i \rangle \rightarrow \delta_{ij} \delta_{nm}$ .

In the very strong coupling limit (e.g, an infinite light-matter coupling), the overlap  $\langle m_j | n_i \rangle$  approaches to zero, effectively eliminating all diabatic electronic couplings  $V_{ij}(\mathbf{R})$ . As such, the polariton Hamiltonian becomes  $\hat{\mathcal{H}}_{\rm pl} = \sum_{i,n_i} \left(V_i(\mathbf{R}) + (n_i + \frac{1}{2})\hbar\omega_{\rm c}\right)|\mu_i,n_i\rangle\langle n_i,\mu_i|$ , where the light and matter are effectively decoupled. This agrees with the recent theoretical analysis of atomic QED systems under the deep strong coupling limit. <sup>50</sup> It also indicates that, as the light-matter coupling goes large, the polariton state

$$|\Psi_J(\mathbf{R})\rangle \to |\mu_i, n_i\rangle \equiv |\mu_i\rangle \otimes |n_i\rangle$$
, (16)

meaning that the polariton state  $|\Psi_J\rangle$  becomes the tensor product of Mulliken-Hush diabatic states with the PFS state. Further, the polariton potential energy surface becomes

$$\mathcal{E}_J(\mathbf{R}) \to V_i(\mathbf{R}) + (n_i + \frac{1}{2})\hbar\omega_{\mathrm{c}},$$
 (17)

which means the polariton state will assume the same potential curvature as the MH diabatic states  $V_i(\mathbf{R})$ , since the photonic energy  $(n_i + \frac{1}{2})\hbar\omega_c$  is **R**-independent.

Eq. 16 and Eq. 17 are considered as the *main theoretical results* in this work. Below, we will use both the atomic cavity QED example, as well as a model molecular cavity QED system to demonstrate its predictive power.

#### Special Case of the Atomic Cavity QED

To give an illustrative and familiar example, let us consider the case of an atom

$$\hat{H}_{\rm M} = E_q |g\rangle\langle g| + E_e |e\rangle\langle e|. \tag{18}$$

where the transition dipole is  $\mu_{eg} = \langle e|\hat{\mu}|g\rangle$ . Note that the permanent dipoles are  $\mu_{ee} = \langle e|\hat{\mu}|e\rangle = 0$ ,  $\mu_{gg} = \langle g|\hat{\mu}|g\rangle = 0$ . Thus, the dipole operator is expressed as

$$\hat{\boldsymbol{\mu}} = \boldsymbol{\mu}_{eg}(|e\rangle\langle g| + |g\rangle\langle e|) \equiv \mu_{eg}(\hat{\sigma}^{\dagger} + \hat{\sigma}) \qquad (19)$$

by defining the creation operator  $\hat{\sigma}^{\dagger} \equiv |e\rangle\langle g|$  and annihilation operator  $\hat{\sigma} \equiv |g\rangle\langle e|$  of the electronic excitation. The atom-cavity PF Hamiltonian becomes  $\hat{H}_{\mathrm{PF}} = \hat{H}_{\mathrm{M}} + \hat{H}_{\mathrm{ph}} + \chi \cdot \mu_{eg}(\hat{\sigma}^{\dagger} + \hat{\sigma})(\hat{a}^{\dagger} + \hat{a}) + \frac{1}{\hbar\omega_{c}}(\chi \cdot \mu_{eg})^{2}$ . Dropping the DSE (the last term) leads to the Rabi model <sup>51</sup>

$$\hat{H}_{\text{Rabi}} = \hat{H}_{\text{M}} + \hat{H}_{\text{ph}} + \chi \cdot \mu_{eg} (\hat{\sigma}^{\dagger} + \hat{\sigma}) (\hat{a}^{\dagger} + \hat{a}), (20)$$

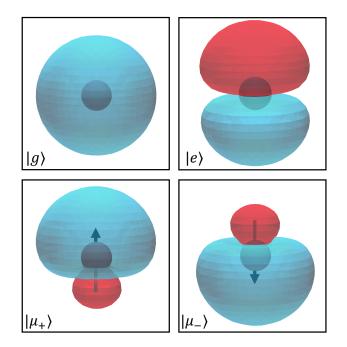

Figure 1: Visualization of an atomic system's wavefunctions in its energy eigenstates ( $|g\rangle$  and  $|e\rangle$ ) and its first two MH diabatic states ( $|\mu_{+}\rangle$  and  $|\mu_{-}\rangle$ ).

where further dropping the counter-rotating terms  $\hat{\sigma}^{\dagger}\hat{a}^{\dagger}$  and  $\hat{\sigma}\hat{a}$  leads to the well-known Jaynes-Cummings model,<sup>52</sup> with the details provided in the Appendix.

For atomic systems where  $\mu_{ee} = \mu_{gg} = 0$ , the the eigenstates of  $\hat{\mu}$ , *i.e.*, the MH diabatic states are

$$|\mu_{\pm}\rangle = [|g\rangle \pm |e\rangle]/\sqrt{2},$$
 (21)

which are commonly referred to as the the qubit states<sup>53–56</sup> in the AMO physics community. Under this basis, the dipole operator becomes

$$\hat{\boldsymbol{\mu}} = \boldsymbol{\mu}_{eg} |\mu_{+}\rangle \langle \mu_{+}| - \boldsymbol{\mu}_{eg} |\mu_{-}\rangle \langle \mu_{-}|, \qquad (22)$$

with the eigenvalue  $\mu_{\pm} = \pm \mu_{eg}$ . Fig. 1 provides a visualization of the wavefunctions for an atomic system in both its energy eigenstates and its MH diabatic states.

Using these diabatic states, the atomic Hamiltonian is expressed as

$$\hat{H}_{\mathcal{M}} = \frac{\Delta}{2} [|\mu_{+}\rangle\langle\mu_{-}| + |\mu_{-}\rangle\langle\mu_{+}|] + E_{g}\hat{\mathbb{1}}_{\mathcal{M}}, \quad (23)$$

where  $\Delta = E_e - E_g$  and  $\hat{1}_{\text{M}}$  is the identity operator for this matter model.

The PFS representation of this model then be-

comes

$$\hat{\mathcal{H}}_{\text{Rabi}} = \sum_{\pm, n_{\pm}, m_{\pm}} \frac{\Delta}{2} \left[ \langle m_{\pm} | n_{\mp} \rangle | \mu_{\mp}, n_{\mp} \rangle \langle m_{\pm}, \mu_{\pm} | \right] + \sum_{\pm, n_{\pm}} \hbar \omega_{c} (n_{\pm} + \frac{1}{2}) | \mu_{\pm}, n_{\pm} \rangle \langle n_{\pm}, \mu_{\pm} | ,$$
(24)

since  $V_{\pm} = 0$ ,  $V_{\pm,\mp} = \Delta/2$ , and there are no nuclear DOFs. As discussed in Ref. 53, by approximating that  $\langle m_{\pm}|n_{\mp}\rangle \approx 0$  for  $m \neq n$  (valid for large couplings), the Hamiltonian in Eq. 24 becomes block diagonal and the eigenenergies and eigenstates can be analytically obtained as follows  $^{53,54}$ 

$$|\Psi_{\pm,n}\rangle = \frac{1}{\sqrt{2}} (|\mu_+, n_+\rangle \pm |\mu_-, n_-\rangle)$$
 (25a)

$$E_{\pm,n} = \hbar\omega_c(n + \frac{1}{2}) + E_g \pm \frac{\Delta}{2} \langle n_- | n_+ \rangle. \quad (25b)$$

It should be noted that this expression uses the notation from Ref. 53. These eigenstates should not be confused with the Jaynes-Cummings (JC) eigenstates (see Eq. 50) which are the exact eigenvectors of the JC Hamiltonian (see Eq. 49).

In the deep strong coupling limit, the overlap between the PFS  $\langle n_-|n_+\rangle \to 0$ . In this case, one can clearly see that the eigenstates  $|\Psi_{\pm,n}\rangle$  become doubly degenerate with  $E_{+,n}=E_{-,n}$  and the MH diabatic states  $|\mu_{\pm},n\rangle$  are the eigenstates of the light-matter Hamiltonian where the corresponding eigenenergies simplify to the energies of these MH states added to the energy of n photons.

# Models and Computational Details

In this paper, we use this Shin-Metiu three-level system<sup>39</sup> to demonstrate two different regimes of ground state modification. To demonstrate the ground state potential modification when coupling a molecule to the cavity, we use the Shin-Metiu<sup>39</sup> single-electron proton-transfer model truncated to three matter levels for the matter Hamiltonian. This model consists of fixed donor and acceptor ions with a proton being transferred between them, yielding one nuclear coordinate. The matter truncation is done in the MH basis, creating a model three-level system with donor (D), acceptor (A), and covalent (C) diabatic states, such that  $\{|\mu_i\rangle\} \in \{|D\rangle, |A\rangle, |C\rangle\}$ .

#### Shin-Metiu model

The Shin-Metiu model<sup>39</sup> is a one-dimensional molecular system that describes a proton-coupled-electron transfer reaction between a donor and an acceptor ion. The model consists of a transferring proton, an electron, and two fixed ions (a donor ion and an acceptor ion). The total Hamiltonian of the molecular system is  $\hat{H}_{\rm M} = \hat{T}_R + \hat{H}_{\rm el}$ , where  $\hat{T}_R = \hat{P}_R^2/2m_{\rm p}$  is the kinetic energy of the transferring proton, with the proton mass  $m_{\rm p}$ . In addition,  $\hat{H}_{\rm el}$  is the electronic Hamiltonian

$$\hat{H}_{\rm el} = \hat{T}_r + \hat{V}_{\rm eN} + \hat{V}_{\rm NN},$$
 (26)

where  $\hat{T}_r = \hat{p}_{\rm r}^2/2m_{\rm e}$  represents the kinetic energy operator of the electron with mass  $m_{\rm e}$ ,  $\hat{V}_{\rm eN}$  describes the interaction between the electron and the three ions through the form of a modified coulomb potential as follows

$$\hat{V}_{eN} = -z_{p}e^{2} \frac{\operatorname{erf}(\frac{|r-R|}{R_{c}})}{|r-R|}$$

$$-z_{D}e^{2} \frac{\operatorname{erf}(\frac{|r-R_{D}|}{R_{c}})}{|r-R_{D}|} - z_{A}e^{2} \frac{\operatorname{erf}(\frac{|r-R_{A}|}{R_{c}})}{|r-R_{A}|},$$
(27)

where r is the position and e=1 a.u. is the fundamental charge, R is the position of the proton, while  $R_{\rm D}$  and  $R_{\rm A}$  are the positions of the static donor and acceptor ion, respectively. Further,  $z_{\rm p}$ ,  $z_{\rm D}$ , and  $z_{\rm A}$  represent the charge of the proton, donor ion, and acceptor ion, respectively. Additionally,  $R_{\rm c}$  characterizes the strength of the modified coulomb interaction between the electron and the ions

The nuclear-nuclear interaction potential  $V_{\rm NN}$  describes the coulomb repulsion between the proton and the static ions as follows

$$V_{\rm NN} = \frac{z_{\rm p} z_{\rm D} e^2}{|R - R_{\rm D}|} + \frac{z_{\rm p} z_{\rm A} e^2}{|R - R_{\rm A}|}$$
 (28)

# Computational Details

In this work, we use the Fourier Grid Hamiltonian (FGH) approach <sup>57,58</sup> to solve the eigenvalue problem of all matter and polariton Hamiltonians. In particular, we use a total of N=2000 grid basis  $\{|r_i\rangle\}$  to describe the electronic degrees of freedom r in the range  $[R_{\rm D}-10,R_{\rm A}+10]$  (with  $\Delta r=0.01$  a.u.), which allows us to solve the adiabatic states of the matter. The matrix elements of the elec-

$m_{ m p}$	1836 (a.u.)	1836 (a.u.)
$m_{ m e}$	1 (a.u.)	1 (a.u.)

tronic Hamiltonian  $\hat{H}_{el}$  in this grid basis  $\{|r_i\rangle\}$  are given by

$$\langle r_i | \hat{H}_{el} | r_j \rangle = \langle r_i | \hat{T}_r + \hat{V}_{eN}(\hat{r}, R) + \hat{V}_{NN}(R) | r_j \rangle$$
  
=  $\langle r_i | \hat{T}_r | r_j \rangle + [\hat{V}_{eN}(r_j, R) + \hat{V}_{NN}(R) | \delta_{ij},$  (29)

where the  $\langle r_i | \hat{T}_r | r_j \rangle$  is given analytically <sup>57,58</sup> as follows

$$\langle r_i | \hat{T}_r | r_j \rangle = \frac{\hbar^2}{2m} \cdot \frac{\pi^2}{3(\Delta r)^2} \left( 1 + \frac{2}{N^2} \right) \delta_{ij}$$

$$+ \frac{\hbar^2}{2m} \cdot \frac{2(-1)^{j-i} \pi^2}{(\Delta r N \sin\left(\frac{\pi(j-i)}{N}\right))^2} (1 - \delta_{ij}).$$
(30)

Directly diagonalizing the matrix of  $\hat{H}_{\rm el}$  at a given nuclear position R in this grid basis gives the accurate adiabatic electronic states, and in this work, we only focus on the lowest three adiabatic states

$$|\Phi_{\alpha}(R)\rangle = \sum_{i} c_{i}^{\alpha}(R)|r_{i}\rangle,$$
 (31)

where  $a \in \{0,1,2\}$ . Further, the matrix elements for dipole moment operator  $\hat{\mu} = \hat{R} + \hat{r}$ , can be computed as

$$\langle r_i | \hat{\mu} | r_j \rangle = \langle r_i | R + \hat{r} | r_j \rangle = (R + r_i) \delta_{ij}.$$
 (32)

After solving for the lowest three adiabatic PESs, we project this dipole operator to the truncated Hilbert space of these adiabatic states, such that  $\hat{\mu} \to \hat{\mathcal{P}}\hat{\mu}\hat{\mathcal{P}}$ , where  $\hat{\mathcal{P}} = \sum_{a=0}^2 |\phi_a(R)\rangle\langle\phi_a(R)|$ . By defining  $\hat{\mathcal{U}}_{\mu}$  in this subspace, we can then find the matrix elements,  $V_i(\mathbf{R})$  and  $V_{ij}(\mathbf{R})$  by transforming  $\hat{H}_{\rm el} \to \hat{\mathcal{U}}_{\mu}^{\dagger}\hat{H}_{\rm el}\hat{\mathcal{U}}_{\mu}$ , where  $V_i(\mathbf{R})$  and  $V_{ij}(\mathbf{R})$  are the diagonal and off-diagonal matrix elements, respectively, in this basis.

Additionally, the overlaps of the shifted Fock

states,  $\langle m_j | n_i \rangle$  are found using the relation <sup>53</sup>

$$\langle m_j | n_i \rangle = \sqrt{\frac{m!}{n!}} \left( \frac{\chi(\mu_i - \mu_j)}{\hbar \omega_c} \right)^{n-m} e^{-\frac{1}{2} \left( \frac{\chi(\mu_i - \mu_j)}{\hbar \omega_c} \right)^2} \cdot L_m^{n-m} \left[ \left( \frac{\chi(\mu_i - \mu_j)}{\hbar \omega_c} \right)^2 \right]$$
(33)

for m < n, where  $L_m^{n-m}$  is an associated Laguerre polynomial.

Using all of the above components, we can solve for the polariton potential energy surface  $\mathcal{E}_j(\mathbf{R})$  of the Hamiltonian  $\hat{\mathcal{H}}_{pl}$  (Eq. 15).

$$\hat{\mathcal{H}}_{\text{pl}}|\Phi_{i}(\mathbf{R})\rangle = \mathcal{E}_{i}(\mathbf{R})|\Phi_{i}(\mathbf{R})\rangle,$$
 (34)

The polaritonic PESs  $\mathcal{E}_j(\mathbf{R})$  can then be calculated by using the values of  $V_i(\mathbf{R})$  and  $V_{ij}(\mathbf{R})$  calculated from the pure matter system (through the above DVR method) and the PFS overlaps (Eq. 33),  $\langle m_j | n_i \rangle$ , and directly diagonalizing the matrix of  $\hat{\mathcal{H}}_{\rm pl}$ . Note that identical results are obtained by solving Eq. 8 using the adiabatic-Fock basis  $|\Phi_{\alpha}(R)\rangle \otimes |n\rangle$ , where  $|\Phi_{\alpha}(R)\rangle$  is the adiabatic states (see Eq. 6) and  $|n\rangle$  is the Fock state for the un-shifted field  $(\hat{a}^{\dagger}\hat{a} + \frac{1}{2})\hbar\omega_c$ .

As expected from our theoretical analysis in Eq. 16, the polariton state approaches the tensor product of the Mulliken-Hush (MH) diabatic states and the PFS states as the light-matter coupling increases. The curvature of the polariton potential energy surface will also approach the MH diabatic states, as indicated in Eq. 17. In particular, for the three-level Shin-Metiu model system studied here, we consider three MH diabatic states, a donor state  $|D\rangle$  where the electron is localized on the donor atom, an acceptor state  $|A\rangle$  where the electron is localized on the acceptor atom, and an atomic state  $|C\rangle$  where the electron is localized on the transferring charged ion (proton). With a strong light-matter coupling strength, at a particular nuclear configuration R, the ground state of the light-matter hybrid will approach one of these diabatic states depending on which of the diabatic energies  $V_i(R) = \langle i|H_{\rm el}|i\rangle$  with  $i \in \{|D\rangle, |A\rangle, |C\rangle\}$ is the lowest.

In this work, we consider two particular sets of parameters, which we refer to as Model I and Model II. The parameters in the molecular Hamiltonian  $\hat{H}_{\rm M}$  are tabulated in Table 1. In Model I, when strongly coupled to the cavity, the ground polariton potential will approach the diabatic state  $|\mathbf{C}\rangle$ ; for model II, the ground polariton potential

approaches the acceptor and donor diabatic states  $|A\rangle$  and  $|D\rangle$ , depending on the nuclear configuration. This will modify the reaction barrier on the ground state. In both cases, the molecular model is coupled to a highly off-resonant cavity with  $\omega_c = 3$  eV (thus operating outside the vibrational strong coupling regime  $^{40,59,60}$ ), and the number of Fock states was treated as a convergence parameter (converged with at most 50 Fock states for Model I and 20 Fock states for Model II).

# Results and Discussion

Fig. 2 presents the results of coupling Model I to the cavity. The diabatic states  $|D\rangle$ ,  $|C\rangle$ , and  $|A\rangle$  in this model are depicted in the top panel of Fig. 2a, whereas the ground adiabatic electronic

states  $|\Phi_0(R)\rangle$  at three nuclear configuration are depicted below the diabatic states. In this model, the covalent diabatic state is lower in energy than the donor and acceptor diabatic states, as shown in Fig. 2b (dashed lines). As a result, the character of the ground adiabatic state is dominated by the covalent diabatic state  $|C\rangle$ , especially near the top of the potential barrier (where  $R \approx 0$ ). In this case, the proton and the electron are transferred simultaneously from the donor ion to the acceptor ion, making this process an adiabatic hydrogen atom transfer reaction. This is schematically illustrated in Fig. 2a, where the adiabatic (bottom panels) and diabatic (top panels) ground state electron distributions are illustrated at the donor (R = -5.5), barrier (R = 0), and acceptor (R = 5.5) nuclear configurations. This shows how the electron follows the proton along the proton transfer coordinate. In Fig. 2b, the adiabatic and diabatic potential energy surfaces are plotted. It can be seen that the two wells in the adiabatic ground state potential energy surface come from the coupling between the donor/acceptor diabats  $|D\rangle$  and  $|A\rangle$ with the covalent diabatic state  $|C\rangle$  through the diabatic couplings  $V_{DC}(R)$  and  $V_{AC}(R)$ .

Fig. 2c depicts the permanent dipole moments of the three MH diabats as a function of R. Note that the transition dipoles among the MH diabats are zero by definition (see Eqn. 9). As expected, the permanent dipole of the covalent state  $|C\rangle$  is flat as the electron density sticks to the transferring proton. On the other hand, the permanent dipoles of the  $|D\rangle$  and  $|A\rangle$  states are linear with respect to the position of the transferring proton as in these states the electron density is localized on the donor/acceptor atom such the permanent dipole is approximately  $\mu_{D/A}(R) \approx R - R_{D/A}$ .

Fig. 2d depicts the potential energy surface for the photon dressed adiabatic states  $|\Phi_{\alpha}, n\rangle$ , as well as the polariton potential associated with the ground state  $|\Psi_{0}\rangle$ . Near the barrier region  $(R \approx 0)$ , the ground adiabatic state coincides with the covalent diabatic state  $|C\rangle$ , where the ground state potential is nearly identical to MH diabatic potential  $V_{\rm C}(R)$  for  $R \approx 0$ . Thus, for this three-level Shin-Metiu system even in the infinite light-matter coupling limit, the ground state potential near the barrier region will not be modified as it is already very close to the MH diabatic state. In contrast, the ground state potential can be expected to get significantly modified near the donor and acceptor wells as the ground state is formed by hybridiz-

ing the  $|\mathrm{D}\rangle$  or  $|\mathrm{A}\rangle$  with the  $|\mathrm{C}\rangle$  states through a diabatic coupling. Increasing light-matter coupling effectively decreases the diabatic coupling  $\langle 0_{\mathrm{C}}|0_{\mathrm{D}}\rangle \cdot V_{\mathrm{DC}}$  due to the decreasing  $\langle 0_{\mathrm{C}}|0_{\mathrm{D}}\rangle$  (with a similar effect for  $\langle 0_{\mathrm{C}}|0_{\mathrm{A}}\rangle \cdot V_{\mathrm{AC}}\rangle$ ). Thus, it will bring the ground state potential closer to the MH diabats' potential energy surface, as suggested in Eq. 17. This means that near ground state potential minima (for  $R\approx -5.5$  and  $R\approx 5.5$ ), the ground state polariton potential will be pushed upwards as it approaches the MH diabats lying above, thus effectively reducing the ground state barrier height.

Another interesting feature of this ground state modification shown here is that it is not sensitive to the cavity frequency  $\omega_{\rm c}$  as long as the photon frequency is not much smaller than the electronic energy gaps. This can be seen by analyzing Eq. 33, where the  $\langle 0_i | 0_i \rangle$  overlap is a function of  $\chi/\omega_c$  (note that  $\chi \propto \omega_c$  such that  $\chi/\omega_c$  is  $\omega_c$ independent), which is photon frequency independent. As such, the overlap  $\langle 0_i | 0_i \rangle$  is photon frequency independent, and the ground state modification also remains independent of photon frequency as long as the photon frequency is not much smaller than the electronic energy gaps. However, when  $\hbar\omega_c \ll (E_e - E_g)$ , in addition to considering the light-matter coupling in terms of  $\langle 0_i | 0_j \rangle \cdot V_{ij}$ , the couplings  $\langle 0_i | n_i \rangle \cdot V_{ij}$  also become relevant because  $E_e - E_g \approx E_e - E_g + n_j \hbar \omega_c$ . Under this circumstance, the effect on the ground polariton state becomes frequency dependence, such as those vibrational strong coupling (VSC) case 36,37 when  $\hbar\omega_{\rm c}\ll (E_e-E_q)$ . On the other hand, when photon frequency is comparable to or larger than electronic transition, the ground state modification can be mainly understood by considering the  $\langle 0_i | 0_i \rangle V_{ii}$ term, and then the cavity modification becomes photon frequency independent.

Model I, presented in Fig. 2, is particularly salient in the context of recent computational work that investigates molecular hydrogen atom transfer reaction landscapes when coupling a molecule strongly to a cavity. <sup>61</sup> In Ref. 61, Pavošević et. al. model the proton-transfer reaction of a malonaldehyde molecule in the strong coupling regime. They found that when using self-consistent QED electronic structure methods (such as QED Hartree-Fock and QED Coupled Cluster level of theory), one observes a decrease in the barrier height of the proton-transfer reaction with electronic strong coupling. Our model through the PFS theory (Eq. 17)

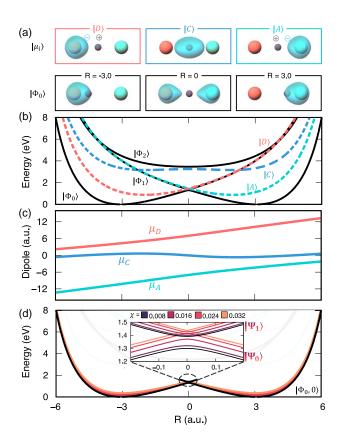

Figure 3: Model II: Shin-Metiu three-level proton transfer model. (a) Visualization of electron charge density for the energy diabats at three different positions and the ground state adiabat at the same positions. (b) Plot of the PESs for the adiabatic states ( $\{|\Phi\rangle\}$ ) and the diabatic states ( $\{|D\rangle, |A\rangle, |C\rangle\}$ . (c) Dipole eigenvalues for each diabatic state as a function of R. (d) Polaritonic ground state PES,  $|\Psi\rangle$ , and first excited state,  $|\Psi\rangle$ , displayed for many coupling strengths.

provides an intuitive explanation for this effect.

Fig. 3 presents a different kind of modification of the ground state polariton potential. The parameters for model II are picked such that the covalent state  $|C\rangle$  lies energetically higher than the  $|D\rangle$ and  $|A\rangle$  states. Thus, the ground adiabatic state is largely composed of  $|D\rangle$  and  $|A\rangle$  states hybridized through the diabatic coupling  $V_{\rm DA}$ . As shown in Fig. 3a, the electron density no longer follows along with the proton, especially in the middle panels of Fig. 3a for  $R \approx 0$ , in contrast to those in Fig. 3. Instead, the charge density tunnels from the donor to the acceptor ion, as the ground adiabatic state sharply changes its character from  $|D\rangle$  to the  $|A\rangle$ state near  $R \approx 0$ . This model can be regarded as an example of a non-adiabatic proton coupled electron transfer (PCET) reaction. Note that the permanent dipoles presented in Fig. 3c are visually similar to the permanent dipoles shown in Fig.2c for model I, as the underlying nature of the MH diabats  $|D\rangle$ ,  $|A\rangle$  and  $|C\rangle$  are the same in both models.

The non-adiabatic transition from the donor to the acceptor state can be modulated by coupling to a cavity, following the same principles using PFS discussed above. As discussed before, the diabatic coupling  $V_{\rm DA} \cdot \langle 0_{\rm D} | 0_{\rm A} \rangle$  will be reduced, which modulates the non-adiabatic transition near the barrier at R=0. In particular, the splitting at the avoided crossing decreases with an increase in the lightmatter coupling strength.<sup>38</sup> This is illustrated in the inset in Fig. 3d, which shows that the splitting gradually decreases with an increase in  $\chi$ . Near the barrier, the lowest two polariton states approach the acceptor and donor diabatic states. In the limit of infinite light-matter coupling, the avoided crossing between the lowest two PES becomes a conical intersection as the donor and acceptor state become decoupled.

These two models demonstrate different forms of ground state modifications, but all due to the same origin of the light-matter interactions that effectively scales down the diabatic couplings. In Model I, the effective barrier height reduces significantly as the coupling increases. In Model II, the avoided crossing between the first two adiabats decreases, approaching a conical intersection. In both cases, the fundamental mechanism is the same: the diabatic couplings between MH diabats decrease due to the decreasing overlap integral of two PFS, and the polariton potential energy surfaces approach the MH diabatic potential (Eq. 16) with an increasing light-matter coupling. Under the infinite light-matter coupling limit, the polariton states reduce to the MH diabats tensor producted with PFSs (Eq. 17). The scaling of the diabatic couplings provides a new strategy to changing the ground state chemical reactivity through electron-photon coupling in contrast to the operating principle of VSC where cavity radiation can modify chemical reactivity through kinetics and dynamical effects. 40,60,62

# Conclusion

Using the Polarized Fock State (PFS) representation, we provide a simple theory to explain how electronic strong coupling can modify the ground state polariton potential. We show that when coupled to the cavity, the diabatic couplings between Mulliken-Hush diabat states (which are the eigenstates of the electronic dipole operator) are modified. Using this theoretical framework, an increasing light-matter coupling will lead to a decrease of the diabatic coupling. In the infinite coupling limit as the diabatic couplings go to zero, the MH diabats tensor product with the polarized Fock states become the eigenstates of the light-matter Hamiltonian (see Eq. 16). Consequently, as the coupling strength increases, the ground state polariton PES approaches the lowest energy matter Mulliken-Hush diabatic state (see Eq. 17). This simple but intuitive theory explains several recently observed ground state modifications due to strong light-matter interactions. <sup>61</sup>

In this paper, we demonstrate with model 3-level Shin-Metiu model systems that this modification of the ground state, either leads to a decrease of the relative barrier height (for Model I in Fig. 2), or a decrease of the avoided crossing between ground and excited states (for Model II in Fig. 3). This novel change in the ground-state chemical reactivity is achieved through electronic strong coupling as opposed to the more common use of vibrational strong coupling for modifying the ground-state chemical reactivity. This work provides a simple but powerful theoretical framework to understand how strong coupling between molecule and cavity can modify ground state reactivities.

# Appendix: Derivation of the Pauli-Fierz QED Hamiltonians

We provide a brief derivation of the Pauli-Fierz QED Hamiltonian. The cavity photon field Hamiltonian under the single-mode assumption is expressed as

$$\hat{H}_{\rm ph} = \hbar \omega_{\rm c} (\hat{a}^{\dagger} \hat{a} + \frac{1}{2}) = \frac{1}{2} (\hat{p}_{\rm c}^2 + \omega_{\rm c}^2 \hat{q}_{\rm c}^2),$$
 (35)

where  $\omega_c$  is the frequency of the mode in the cavity,  $\hat{a}^{\dagger}$  and  $\hat{a}$  are the photonic creation and annihilation operators, and  $\hat{q}_c = \sqrt{\hbar/2\omega_c}(\hat{a}^{\dagger} + \hat{a})$  and  $\hat{p}_c = i\sqrt{\hbar\omega_c/2}(\hat{a}^{\dagger} - \hat{a})$  are the photonic coordinate and momentum operators, respectively. Choosing the Coulomb gauge,  $\nabla \cdot \hat{\mathbf{A}} = 0$ , the vector potential becomes purely transverse such that  $\hat{\mathbf{A}} = \hat{\mathbf{A}}_{\perp}$ . Under the long-wavelength approximation,

$$\hat{\mathbf{A}} = \mathbf{A}_0 (\hat{a} + \hat{a}^{\dagger}) = \mathbf{A}_0 \sqrt{2\omega_{\rm c}/\hbar} \,\,\hat{q}_{\rm c}, \qquad (36)$$

where  $\mathbf{A}_0 = \sqrt{\hbar/2\omega_c\varepsilon_0\mathcal{V}} \hat{\mathbf{e}}$ , with  $\mathcal{V}$  as the quantization volume inside the cavity,  $\varepsilon_0$  as the permittivity, and  $\hat{\mathbf{e}}$  as the unit vector of the field polarization.

The minimal coupling QED Hamiltonian in the Coulomb gauge (the "p · A" form) is expressed as

$$\hat{H}_{C} = \sum_{j} \frac{1}{2m_{j}} (\hat{\mathbf{p}}_{j} - z_{j}\hat{\mathbf{A}})^{2} + \hat{V}(\hat{\mathbf{x}}) + \hat{H}_{ph}, \quad (37)$$

where  $\hat{\mathbf{p}}_j = -i\hbar \boldsymbol{\nabla}_j$  is the *canonical* momentum operator. We further introduce the Power-Zienau-Woolley (PZW) gauge transformation operator  $^{47,48}$  as

$$\hat{U} = \exp\left[-\frac{i}{\hbar}\hat{\boldsymbol{\mu}}\cdot\hat{\mathbf{A}}\right] = \exp\left[-\frac{i}{\hbar}\hat{\boldsymbol{\mu}}\cdot\mathbf{A}_0(\hat{a}+\hat{a}^\dagger)\right].$$
(38)

The PZW transformation operator can also be expressed as  $\hat{U} = \exp\left[-\frac{i}{\hbar}\sqrt{2\omega_{\rm c}/\hbar}\hat{\boldsymbol{\mu}}\mathbf{A}_0\hat{Q}_{\rm c}\right] = \exp\left[-\frac{i}{\hbar}(\sum_j z_j\hat{\mathbf{A}}\mathbf{x}_j)\right]$ . Recall that a momentum boost operator  $\hat{U}_{\rm p} = e^{-\frac{i}{\hbar}p_0\hat{q}}$  boosts  $\hat{p}$  by the amount of  $p_0$ , such that  $\hat{U}_{\rm p}\hat{O}(\hat{p})\hat{U}_{\rm p}^{\dagger} = \hat{O}(\hat{p} + p_0)$ . Hence,  $\hat{U}$  simultaneously boosts the photonic momentum  $\hat{p}_c$  by  $\sqrt{2\omega_{\rm c}/\hbar}\hat{\boldsymbol{\mu}}\mathbf{A}_0$  and the matter momentum  $\hat{\mathbf{P}}_j$  by  $z_j\hat{\mathbf{A}}$ . Using  $\hat{U}^{\dagger}$  to boost the matter momentum, one can show that

$$\hat{H}_{\rm C} = \hat{U}^{\dagger} \hat{H}_{\rm M} \hat{U} + \hat{H}_{\rm ph}, \tag{39}$$

hence  $\hat{H}_{\rm C}$  can be mathematically obtained <sup>63</sup> by a momentum boost with the amount of  $-z_j\hat{\mathbf{A}}$  for  $\hat{\mathbf{P}}_j$ , then adding  $\hat{H}_{\rm ph}$ .

The QED Hamiltonian under the *dipole* gauge (the "d  $\cdot$  E" form <sup>47,64</sup>) can be obtained by perform-

ing the PZW transformation on  $\hat{H}_{\rm C}$  as follows

$$\hat{H}_{D} = \hat{U}\hat{H}_{C}\hat{U}^{\dagger} = \hat{U}\hat{U}^{\dagger}\hat{H}_{M}\hat{U}\hat{U}^{\dagger} + \hat{U}\hat{H}_{ph}\hat{U}^{\dagger}$$
(40)  
$$= \hat{H}_{M} + \hbar\omega_{c}(\hat{a}^{\dagger}\hat{a} + \frac{1}{2}) + i\omega_{c}\hat{\boldsymbol{\mu}}\mathbf{A}_{0}(\hat{a}^{\dagger} - \hat{a})$$
$$+ \frac{\omega_{c}}{\hbar}(\hat{\boldsymbol{\mu}}\mathbf{A}_{0})^{2}$$

where we have used Eq. 39 to express  $\hat{H}_{\rm C}$ , and the last three terms of the above equation are the results of  $\hat{U}\hat{H}_{\rm ph}\hat{U}^{\dagger}$ . Using  $\hat{q}_{\rm c}$  and  $\hat{p}_{\rm c}$ , one can instead show that

$$\hat{H}_{\rm D} = \hat{H}_{\rm m} + \frac{1}{2}\omega_{\rm c}^2\hat{q}_{\rm c}^2 + \frac{1}{2}(\hat{p}_{\rm c} + \sqrt{2\omega_{\rm c}/\hbar}\hat{\boldsymbol{\mu}}\mathbf{A}_0)^2, (41)$$

because the PZW operator boosts the photonic momentum  $\hat{p}_c$  by  $\sqrt{2\omega_c/\hbar}\hat{\boldsymbol{\mu}}\mathbf{A}_0$ . The term  $\frac{\omega_c}{\hbar}(\hat{\boldsymbol{\mu}}\mathbf{A}_0)^2$  is commonly referred to as the dipole self-energy (DSE).

The Pauli-Fierz (PF) QED Hamiltonian  $^{9,43,44}$  can be obtained by using a unitary transformation  $\hat{U}_{\phi} = \exp\left[i\frac{\pi}{2}\hat{a}^{\dagger}\hat{a}\right]$  on  $\hat{H}_{\rm D}$ . This is effectively a  $\pi/2$  rotation in the phase space of the photonic DOF. To evaluate this, we use the following Baker-Campbell-Hausdorff (BCH) identity

$$e^{\hat{A}}\hat{B}e^{-\hat{A}} = \hat{B} + [\hat{A}, \hat{B}] + \frac{1}{2!}[\hat{A}, [\hat{A}, \hat{B}]] + \dots$$
 (42)

Using the fundamental commutator  $[\hat{a}^{\dagger}, \hat{a}] = -1$ , we have  $[\hat{a}^{\dagger}\hat{a}, \hat{a}] = \hat{a}^{\dagger}[\hat{a}, \hat{a}] + [\hat{a}^{\dagger}, \hat{a}]\hat{a} = -\hat{a}$ . Denoting  $\hat{U}_{\phi} = \exp[i\phi\hat{a}^{\dagger}\hat{a}] = e^{-\hat{A}}$  (with  $\phi = \frac{\pi}{2}$ ),  $\hat{A} = -i\phi\hat{a}^{\dagger}\hat{a}$ . From the BCH identity, we have

$$e^{-i\phi\hat{a}^{\dagger}\hat{a}}\hat{a}e^{i\phi\hat{a}^{\dagger}\hat{a}}$$
(43)  
=  $\hat{a} - i\phi[\hat{a}^{\dagger}\hat{a}, \hat{a}] + \frac{1}{2!}(-i\phi)^{2}[\hat{a}^{\dagger}\hat{a}, [\hat{a}^{\dagger}\hat{a}, \hat{a}]] + \dots$   
=  $\left(1 + (-i\phi)(-1) + \frac{1}{2!}(-i\phi)^{2}(-1)^{2} + \dots\right)\hat{a}$   
=  $e^{i\phi}\hat{a}$ 

Similarly, we have  $e^{-i\phi\hat{a}^{\dagger}\hat{a}}\hat{a}^{\dagger}e^{i\phi\hat{a}^{\dagger}\hat{a}} = e^{-i\phi}\hat{a}^{\dagger}$ . Choosing  $\phi = \frac{\pi}{2}$  results in  $\hat{U}_{\phi}^{\dagger}\hat{a}\hat{U}_{\phi} \rightarrow i\hat{a}$  and  $\hat{U}_{\phi}^{\dagger}\hat{a}^{\dagger}\hat{U}_{\phi} \rightarrow -i\hat{a}^{\dagger}$ . Using these results, and applying  $\hat{U}_{\phi}$  on  $\hat{H}_{D}$ , we have the PF Hamiltonian as

follows

$$\hat{H}_{PF} = \hat{U}_{\phi} \hat{H}_{D} \hat{U}_{\phi}^{\dagger} \qquad (44)$$

$$= \hat{H}_{m} + \hbar \omega_{c} (\hat{a}^{\dagger} \hat{a} + \frac{1}{2}) + \mathbf{A}_{0} \omega_{c} \hat{\boldsymbol{\mu}} (\hat{a} + \hat{a}^{\dagger})$$

$$+ \frac{\omega_{c}}{\hbar} (\mathbf{A}_{0} \hat{\boldsymbol{\mu}})^{2}$$

$$= \hat{H}_{m} + \frac{1}{2} \hat{p}_{c}^{2} + \frac{1}{2} \omega_{c}^{2} (\hat{q}_{c} + \frac{\mathbf{A}_{0} \hat{\boldsymbol{\mu}}}{\sqrt{\hbar} \omega})^{2},$$

where the coupling constant is  $\frac{A_0}{\sqrt{\hbar}\omega_c} = \sqrt{\frac{2}{\hbar\omega_c^3}}\chi$  as we used in Eq. 2. Note that we have used the fact that  $\hat{U}_{\phi}\hat{H}_{\rm M}\hat{U}_{\phi}^{\dagger} = \hat{H}_{\rm M}$ , *i.e.*,  $\hat{U}_{\phi}$  is identity for the matter DOFs. Hence, the role of  $\hat{U}_{\phi}$  is to switch  $\hat{p}_c$  and  $\hat{q}_c$ , since for a photon field, they are interchangeable due to the pure harmonic nature of the quantized field. The PF Hamiltonian has the advantage as a pure real Hamiltonian and the photonic DOF can be viewed  $^{9,44}$  and computationally treated  $^{65,66}$  as "nuclear coordinates".

In quantum optics, a two-level atom coupled to a single model in an optical cavity is a well studied subject. This leads to well-known model Hamiltonians, such as the Rabi Model and the Jaynes-Cummings Model. Since these two models are also widely used in recent investigations of polariton chemistry, here we briefly derive them from the PF Hamiltonian.

We consider a molecule with two electronic states

$$\hat{\mathcal{H}}_{M} = \hat{T} + E_{g}(R)|g\rangle\langle g| + E_{e}(R)|e\rangle\langle e|, \qquad (45)$$

and the transition dipole is  $\mu_{eg} = \langle e|\hat{\mu}|g\rangle$ . Note that the permanent dipoles in a molecule  $\mu_{ee} = \langle e|\hat{\mu}|e\rangle$ ,  $\mu_{gg} = \langle g|\hat{\mu}|g\rangle$  are not necessarily zero, as oppose to the atomic case where they are always zero. Hence, it is not always a good approximation to drop them.

The Rabi model assumes that one can drop the permanent dipoles, and leads to the dipole operator expression in the subspace  $\hat{\mathcal{P}} = |g\rangle\langle g| + |e\rangle\langle e|$  as follows

$$\hat{\mathcal{P}}\hat{\boldsymbol{\mu}}\hat{\mathcal{P}} = \boldsymbol{\mu}_{eg}(|e\rangle\langle g| + |g\rangle\langle e|) \equiv \boldsymbol{\mu}_{eg}(\hat{\sigma}^{\dagger} + \hat{\sigma}), \quad (46)$$

where we have defined the creation operator  $\hat{\sigma}^{\dagger} \equiv |e\rangle\langle g|$  and annihilation operator  $\hat{\sigma} \equiv |g\rangle\langle e|$  of the electronic excitation. The PF Hamiltonian (Eq. 44) in the subspace  $\hat{\mathcal{P}}$  thus becomes

$$\hat{\mathcal{H}}_{PF} = \hat{\mathcal{H}}_{M} + \hat{H}_{ph} + \chi \cdot \mu_{eg} (\hat{\sigma}^{\dagger} + \hat{\sigma}) (\hat{a}^{\dagger} + \hat{a}) + \frac{1}{\hbar \omega_{c}} (\chi \cdot \mu_{eg})^{2}.$$
(47)

Dropping the DSE (the last term) from Eq. 47 leads to the Rabi Model

$$\hat{\mathcal{H}}_{\text{Rabi}} = \hat{\mathcal{H}}_{\text{M}} + \hat{H}_{\text{ph}} + \chi \cdot \mu_{eq} (\hat{\sigma}^{\dagger} + \hat{\sigma}) (\hat{a}^{\dagger} + \hat{a}). \tag{48}$$

Dropping both the DSE and the counter-rotating terms  $\hat{\sigma}^{\dagger}\hat{a}^{\dagger}$  and  $\hat{\sigma}\hat{a}$  leads to the well-known Jaynes-Cummings Model<sup>52</sup> as follows

$$\hat{\mathcal{H}}_{JC} = \hat{\mathcal{H}}_{M} + \hat{H}_{ph} + \chi \cdot \mu_{eq} (\hat{\sigma}^{\dagger} \hat{a} + \hat{\sigma} \hat{a}^{\dagger}). \tag{49}$$

The eigenstates of the JC model are analytically available, expressed as follows

$$|+,n\rangle = \cos\Theta |e,n\rangle + \sin\Theta |g,n+1\rangle,$$
 (50a)

$$|-,n\rangle = -\sin\Theta |e,n\rangle + \cos\Theta |g,n+1\rangle$$
 (50b)

where  $\Theta = \frac{1}{2} \tan^{-1} [2\hbar g_c \sqrt{n+1}/(\hbar \omega_c - \Delta E)]$  is the mixing angle, and  $\Delta E = E_e - E_q$  is the energy gap.

The limitations of these two models are thoroughly discussed in our recent work on Polariton mediated charge transfer <sup>46</sup> and polariton mediated photo-dissociation dynamics of diatomic molecule. <sup>38</sup>
